Hemostasis is the physiological process by which bleeding ceases. Hemostasis involves three basic steps: vascular spasm, the formation of a platelet plug, and coagulation, in which clotting factors promote the formation of a fibrin clot. Fibrinolysis is the process in which a clot is degraded in a healing vessel. Anticoagulants are substances that oppose coagulation. They are important in

We have also given more information on physiology of the players involved in hemostasis (platelets this is under physiology in the hematology section) and various physiologic and pharmacologic inhibitors of hemostasis. [Physiology of Hemostasis and Coagulation Cascade | Medical ...](#)

Primary Hemostasis. Primary hemostasis refers to the first phase of the hemostasis process that stops bleeding. It is a result of the interaction between the circulating platelets, the blood vessel wall, and adhesive proteins leading to the formation of the initial platelet plug.
